RANDOMISATION INFORMATION

Telephone Randomisation Service Number

Web Address

www.charttrials.abdn.ac.uk/ethos

Inclusion Criteria

- · Patients with grade II, III or IV haemorrhoids
- · Patients aged 18 years or older
- Written informed consent obtained

Exclusion Criteria

- Previous surgery for haemorrhoids (except RBL or HALO)
- Previous surgery for sphincter injury, or symptomatic incontinence
- Peri-anal sepsis
- · Known inflammatory bowel disease
- · Malignant gastrointestinal disease, within the last five years
- · Medically unfit for surgery or for completion of the trial
- Pregnant women

Dear Dr GPSName

eTHoS (either Traditional Haemorrhoidectomy or Stapled)

Patient: Title FName SName Ref No DOB Address1 Address2 Address3 Address4 PostCode

A multicentre UK-wide research study, funded by the National Institute for Health Research Health Technology Assessment Programme is investigating which haemorrhoidal operations are the most clinically and cost-effective for patients with haemorrhoids grade II, III and IV. CentreHosp is one of the participating sites. The trial is needed because there is uncertainty about which type of surgery (stapled haemorrhoidopexy or conventional excisional surgery) is most effective for these patients.

All participants who consent will be followed up and those who are eligible will be randomised to a particular type of surgery. Patients who have grade II (and who have already failed two episodes of rubber band ligation), grade III and IV haemorrhoids are included. We are following up patients after their operations, initially for two years, but hopefully also in the longer term, to identify recurrence rates. More detailed information about the study is provided overleaf.

Your patient has agreed to join the study. He/She has been randomised to one of the surgery groups. We will carry out postal follow up (from our study office in Aberdeen) by asking participants to complete questionnaires before surgery and at approximately 1, 3, 6 weeks and 12, 24 and 60 months after surgery. The questionnaires ask about general health and use of the health service as well as specific information about incontinence and haemorrhoidal symptoms.

We should not normally need to obtain any information from you. However, we would be grateful if you could contact telephone number or email ethos@abdn.ac.uk if your patient changes address, is too ill to continue taking part, has an adverse event following their haemorrhoid surgery or dies.

If you would like to discuss any aspect of our trial, or require any further details, please do not hesitate to contact the eTHoS Study Office.

Yours sincerely

Jessica Wood eTHoS Trial Manager Prof. Angus Watson eTHoS Chief Investigator

Version 1.2, February 2015

eTHoS GP INFORMATION SHEET

Title of project

Clinical and cost-effectiveness of two main treatment options for the surgical management of Haemorrhoids grade II, III and IV.

Background

Haemorrhoids are common in all age groups from mid-teens onwards. In England in 2006/2007 approximately 25,000 haemorrhoidal procedures were performed as hospital day-case or inpatient admissions, resulting in significant calls on health service resources. The treatment of haemorrhoidal disease is directed at relieving its related symptoms.

There are two major surgical treatments for haemorrhoids: the conventional excisional haemorroidectomy (traditional surgery) and the stapled haemorrhoidopexy. Improved understanding of the pathogenesis of haemorrhoids, increasing belief in the importance of preserving the anal cushions and greater awareness of the high incidence of complications associated with excisional haemorrhoidectomy led to the invention of the stapled haemorrhoidopexy procedure.

Two recent systematic reviews and an HTA monograph compared the two main surgical procedures, revealing that 95% of patients who received stapled surgery had less pain in the immediate post-operative period compared with the traditional surgery but equivalent complication and pain rates occurred with both procedures at day 21. Other potential advantages of stapled over conventional surgery include a reduction of operating time, hospital stay and time to return to work. However, uncertainties around complication rates and recurrence of symptoms and costs precludes its widespread use across the NHS. Over the long term there was a significantly increased rate of residual prolapse requiring re-intervention with stapled haemorrhoidopexy. eTHoS is therefore investigating what is the best surgical treatment for patients who have haemorrhoids grade II (with two episodes of rubber band ligation), III and IV who require surgery.

Brief outline of the study

Ethical approval has been obtained for this study Written consent has been obtained from participants. Participants will be reviewed in outpatients approximately six weeks after their surgery. Participants are sent postal questionnaires at approximately 1, 3 and 6 weeks and 12 and 24 months after their operation. Our main interest is in the improvement of haemorrhoidal symptoms, as reported by the patients themselves.
